

X-Ray Examination Report

Report Date:	2025-12-15
Radiologist:	Dr. Youssef Masmoudi, MD
Patient Name:	Karim Chaabane
Patient ID:	24789103
Date of Birth:	12 November 1978
Age:	47 years
Gender:	Male
Examination Date:	2025-12-15
Examination Type:	X-Ray Lumbar Spine (AP and Lateral views)
Projection:	Anteroposterior (AP) and Lateral
Technique:	Digital radiography, standard exposure

Clinical Indication

Chronic low back pain for 6 months, radiating to the right posterior thigh intermittently. Pain worsens with prolonged standing and forward bending. No history of trauma, no red flags (no bowel/bladder dysfunction, no weight loss, no fever). Previous abdominal ultrasound (2025-12-16) showed mild hepatic steatosis.

Findings

- Alignment: Normal lumbar lordosis preserved. No evidence of spondylolisthesis.
- Vertebral bodies: Normal height and alignment of L1 to L5. No compression fractures or lytic/sclerotic lesions.
- Disc spaces: Mild disc space narrowing at L4-L5 and L5-S1 levels. No significant narrowing at other levels.

- Facet joints: Mild degenerative changes (sclerosis and minimal osteophyte formation) at L4-L5 and L5-S1 bilaterally.
- Pedicles and spinous processes: Intact, no abnormalities.
- Sacroiliac joints: Normal joint space, no erosions or ankylosis.
- Soft tissues: No abnormal paraspinal masses or calcifications. Psoas shadows normal.
- No evidence of bony destructive lesions or malignancy.

Impression

1. Mild degenerative disc disease at L4-L5 and L5-S1 with associated mild facet joint osteoarthritis.
2. No evidence of acute fracture, instability, or significant spinal canal stenosis on plain radiographs.
3. No red flag signs on imaging.

Clinical correlation recommended. Conservative management (physiotherapy, core strengthening, weight management, NSAIDs as needed) advised. If symptoms persist or worsen, consider MRI lumbar spine for further evaluation of disc pathology and nerve root compression.
